

Electron Microprobe Analyses of Rock-forming Minerals  
in the Sanbagawa Metamorphic Rocks from  
the Ayukawa-Sanbagawa Area, Kanto  
Mountains, Central Japan

Atsushi Miyashita

Seikei High School,  
3-10-13 Kichijoji-kitamachi, Musashino-shi, Tokyo, 180 Japan

**Abstract** Representative chemical compositions of rock-forming minerals in the Sanbagawa metamorphic rocks from the Ayukawa-Sanbagawa area, Kanto Mountains, are tabulated along with their brief descriptions. They include more than 200 electron microprobe analyses of silicate and oxide minerals. In addition to the bulk chemical compositions of metamorphic rocks, mineral assemblages including heavy minerals are presented here. They are basic data for petrological discussions of the metamorphic rocks in the Kanto Mountains.

**Key words:** metamorphic rocks, graphite, garnet, thermometry, mineral assemblage.

### Introduction

The Sanbagawa metamorphic belt is a typical intermediate high-pressure type terrain. It extends about 800 km along the southwestern portion of the Japanese island arc on the Pacific Ocean side. Many workers have been engaged in the petrology of the Sanbagawa metamorphic rocks, especially in central Shikoku, for the last thirty years (e.g. Banno, 1964; Banno & Sakai, 1989). They presented the detailed data for chemistry of rock-forming minerals (Higashino *et al.*, 1981, 1984; Aiba *et al.*, 1984).

The Kanto Mountains is located at the eastern end of the Sanbagawa metamorphic belt. Koto (1888) first established the geological framework of this region and named the schists “Sambagawan” after the name of a small valley in the west of Onishi-machi, Gunma Prefecture. Seki (1958) and Toriumi (1975) studied the metamorphic zonation of low grade region with the detailed description of constituent minerals. Recently, Tokuda (1986), Hirajima and Banno (1989), Hashimoto *et al.* (1992) and Makimoto and Takeuchi (1992) presented the tectonic models for the Sanbagawa metamorphic rocks in the Kanto Mountains. However, the petrography of higher grade part has not been published by any authors yet. This paper gives the petrographical basis of the Sanbagawa metamorphic rocks in the Kanto Mountains, especially focused on the data of the

electron microprobe analyses on the rock-forming minerals in the higher grade pelitic schists.

### Outline of Geology and Petrography

The Ayukawa-Sanbagawa area is situated in northern part of the Kanto Mountains (Fig. 1). The localities of the analyzed samples are shown in Fig. 2. The rocks studied here are registered in the rock collection of the petrology division of the National Science Museum.

In the Kanto Mountains, Sanbagawa, Mikabu and Chichibu belts show a zonal arrangement from north to south with ascending stratigraphic order. The Chichibu belt is composed mainly of trench-fill sediments, and is weakly metamorphosed. The Mikabu belt, so-called Mikabu greenrock complex is considered to

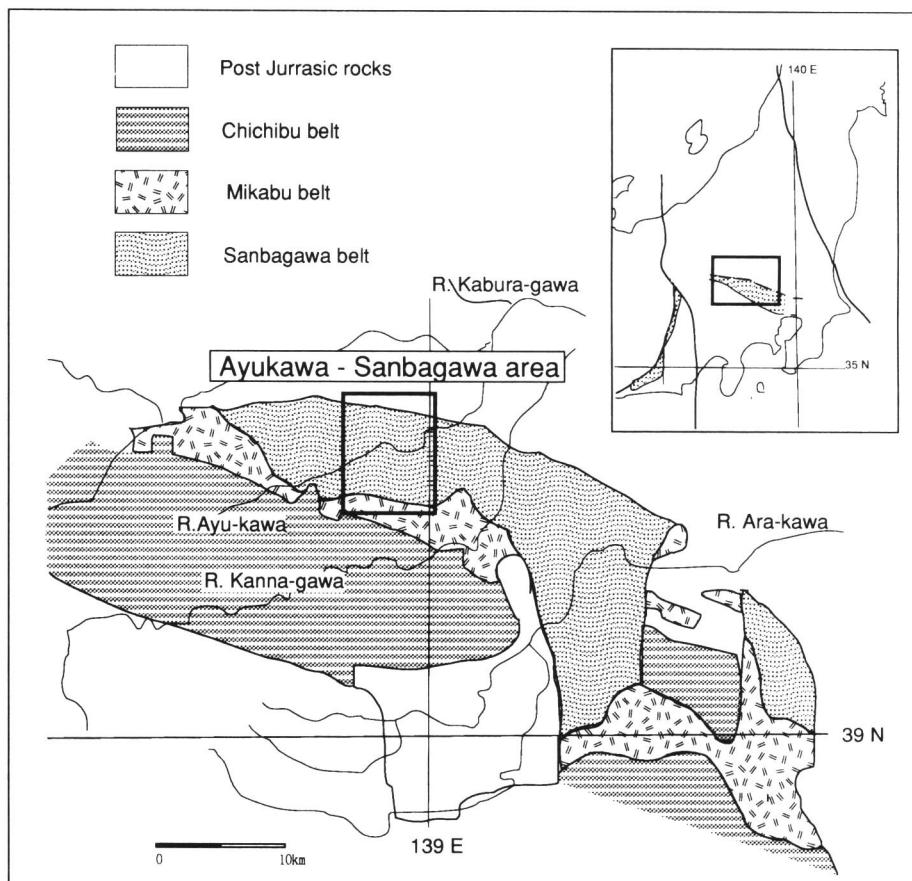

Fig. 1. Geological frameworks of the Kanto Mountains.

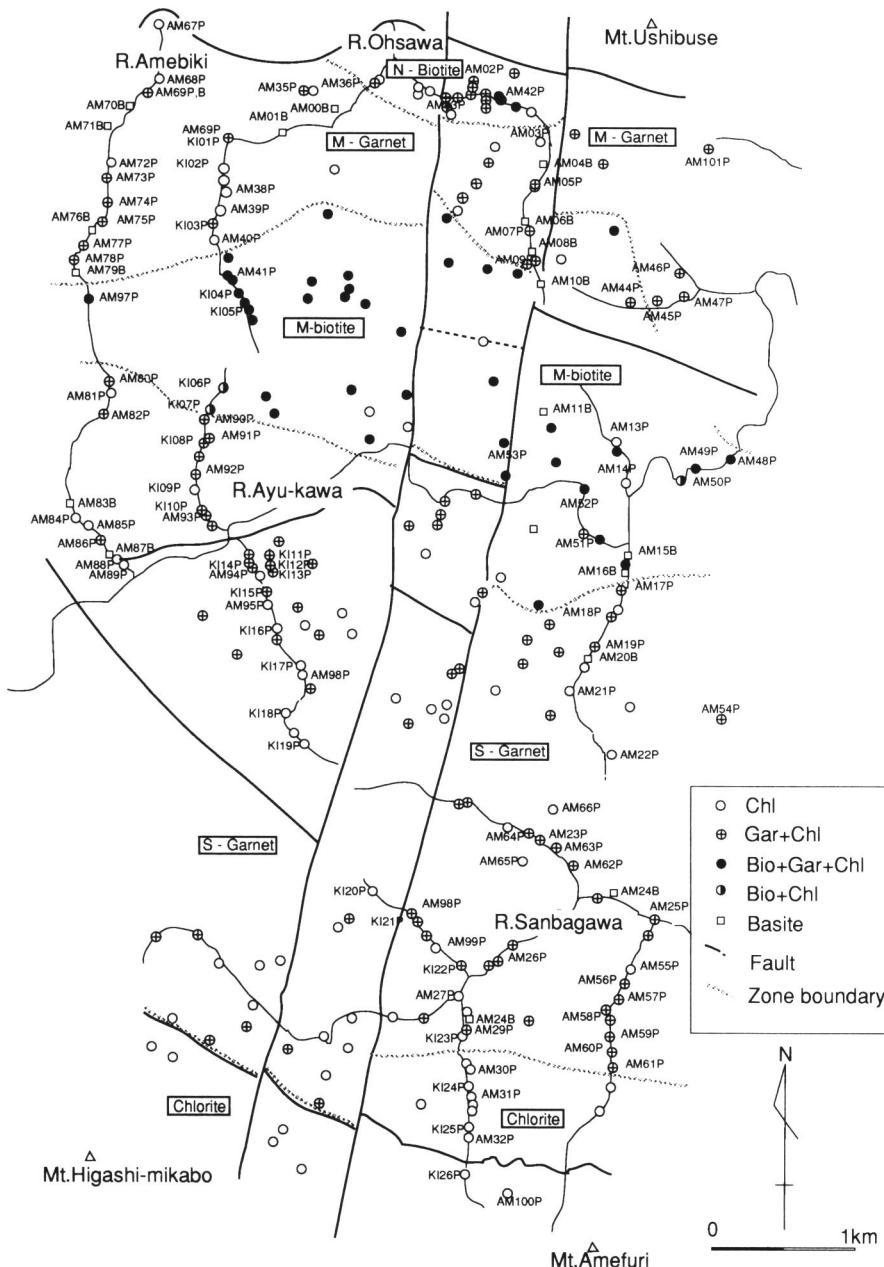

Fig. 2. Locality map in the Ayukawa-Sanbagawa area and division of chlorite, garnet and biotite zones.

be olistostromal melange of blocks and clasts of basic rocks, and is derived parentally from igneous part of the oceanic crust. The petrography and chemistry of the Mikabu belt in this area are summarized by Uchida (1981). The Sanbagawa belt consists dominantly of metapelites, intercalated with metabasites and meta-siliceous rocks, with a small amount of lenticular serpentinite. The Sanbagawa belt in the studied area has an apparent geological structure with a simple monocline trending EWE-WSW and dipping from 30°S to 50°S. Metamorphic grade increases from the Chichibu to the Sanbagawa belt. It is pumpellyite-actinolite facies to sodic-pyroxene chlorite facies in the Chichibu belt and up to albite-epidote amphibolite facies in the Sanbagawa belt (Seki, 1958, Toriumi, 1975; Hirajima & Banno, 1989).

On the basis of the mineral assemblage in metapelite in central Shikoku, the Sanbagawa schists is divided into three mineral zones, *i.e.* chlorite, garnet and biotite zones in ascending order of metamorphic grade. In the Ayukawa-Sanbagawa area, chlorite zone occurs only at the southern part (Fig. 2). Garnet zone is subdivided into the southern and middle garnet zones. Biotite zone is also subdivide to the middle and northern biotite zones. This complicated arrangement of zone is due to tectonic stacking of four slabs of sub-units (Miyashita, in preparation). They are bordered by thrust.

### Analytical Procedure

The electron microanalyser used for the analyses is JEOL 5400 with fully quantitative Link Systems model 2000 energy-dispersive spectrometer, EDS, of the Natural Science Museum, Tokyo. The analytical conditions are the same as those reported by Yokoyama *et al.* (1993). The X-ray diffractometer used for the analyses of crystallinity of carbonaceous matter is Rigaku Rint 2000 of the Natural Science Museum, Tokyo. The sample preparation and the method of measurement are after Tagiri (1981). X-ray fluorescence analyses of major elements in the meta-pelites are produced by Rigaku model 3040 of the Waseda University.

### Bulk Rock Chemistry

Bulk chemical compositions of 20 metapelites (Appendix 1) are obtained to check compositional effects of partition coefficients among minerals. Although the compositions of metapelites of the Kanto Mountains are lower in FeO and MgO contents than those of average chemical composition of metamorphosed pelitic rocks (Shaw, 1956), they are similar to those from the central Shikoku (Banno, 1964; Goto *et al.*, 1996). Modal proportions of representative minerals of the metapelites mentioned above are shown in Appendix 2. They are identified

under the optical microscope, whereas minor heavy minerals including opaque minerals listed in Appendix 3 are identified under electron microscope with EDS.

### Mineralogy

**Garnet:** Garnet in the metapelite is critical mineral for the zonal mapping of the Sanbagawa metamorphic rocks. It usually shows chemical zoning with regard to MnO, FeO, CaO and MgO. In the southern garnet zone, garnet shows normal zoning where MnO decreases from core to rim. Whereas, in the middle garnet zone, the complex zoned garnets are frequently observed. Detrital garnets (Higashino & Takasu, 1982) are found from some metapelites. They are always MgO-rich and are included in the MgO-poor garnets which were formed by the Sanbagawa metamorphism. There is usually distinct chemical discontinuity at the boundary between them. Chemical composition of the garnet rim is listed in Appendix 4. Each data is average composition of analyses of several points.

**Chlorite:** Chlorite is one of main constituent minerals in the metapelite. The optical character of chlorite is mostly negative in the studied area. The chemical heterogeneity in chlorite is recognized. Chemical composition of the average of several analyses at the most MgO-rich portion is listed in Appendix 5. MgO-rich chlorite is considered to be equilibrated with garnet rim during progressive metamorphism (Higashino, 1975).

**Biotite:** Biotite in the metapelite is also critical mineral for the zonal mapping of the Sanbagawa metamorphic rocks. Biotite is usually brown in color under microscope, and almost homogeneous within an individual grain. In the Kanto Mountains, green biotite is often found in the hematite-bearing siliceous schists and the hematite-bearing metabasite. The green biotite is poor in FeO and rich in MgO compared with brown biotite. Appendix 6 includes analyses of biotites both in the northern and middle biotite zones.

**White mica:** White mica is phengitic. Paragonite has not been found in the Kanto Mountains. Two types of heterogeneity in phengite are recognized. One is a zoning with Na-rich core and Na-poor rim, and another shows Si-rich core and Al-rich rim. Hirajima *et al.* (1992) obtained K-Ar age from white mica. The former type mica shows 67–53 Ma, and the latter shows 87–66 Ma. The FeO+MgO content of phengite is lower in the northern biotite zone than those in the other mineral zones. Chemical compositions of white micas are listed in Appendix 7.

**Amphibole:** Amphibole has not been observed in the metapelites from the Kanto Mountains, different from appearance of amphibole in the highest grade pelites from central Shikoku. In the metabasite of the chlorite zone, amphibole is actinolite and sodic amphibole. In the higher grade zone, amphibole is from actinolite to actinolitic hornblende in the Fe-oxide bearing metabasites (Hashi-

moto & Funakoshi, 1991). In the meta-siliceous rock of the middle biotite zone, Mn-rich amphibole occurs with Mn-rich sodic pyroxene and spessartine garnet. Chemical compositions of amphiboles in the metabasites and meta-siliceous rock are listed in Appendix 8.

*Plagioclase:* Plagioclase is also one of the major phases in the metapelites. Albite porphyroblast occurs in both the metapelite and basite. Such rocks are called “spotted schists”. Although they occur mostly in the higher grade zone of this area, the relationships between the metamorphic grade and the grain size of albite porphyroblast has not been solved yet. Plagioclase is almost pure albite in the garnet zone and shows compositional zoning with a small variation of anorthite content. Both simple and complex types of zonal structure described from the central Sikoku (Otsuki, 1980) are also recognized in this area. In the biotite zone, albite porphyroblast has oligoclase rim. Its maximum An content is from 10 to 13 in the middle biotite zone, and from 17 to 24 in the northern biotite zone. The latter is free from inclusions, different from the porphyroblastic oligoclase of oligoclase-biotite zone in central Shikoku. The chemical compositions of plagioclases both in the northern and middle biotite zones are listed in Appendix 9.

*Epidote:* Epidote group minerals are common in the metabasite. Piedmontite is often found in the meta-siliceous rocks. However, they are minor constituent in the metapelite. Epidote in the metapelite has frequently allanite core where total amount of rare-earth elements such as Ce, La, and Nd exceeds 20 wt%. Analytical results of epidote group minerals in the metapelites are listed in Appendix 10.

*Ilmenite:* Titanite, rutile and ilmenite occur mostly as discrete grains, but composite aggregate composed of the minerals is common. In central Shikoku, ilmenite is only stable phase in the biotite zone and is homogeneous formed at the prograde metamorphism (Itaya & Banno, 1980). On the other hand, ilmenite is rarely found in the metapelite from the Kanto Mountains. Chemical compositions of ilmenites in the metapelites are shown in Appendix 10.

*Carbonaceous matter:* Metapelite contains abundant carbonaceous material. Its crystalline degree changes continuously from amorphous to fully ordered state with increasing metamorphic temperature (Tagiri, 1981). The degree of graphitization is measured by the X-ray diffraction method. Representative data are presented in Appendix 11.

### Acknowledgments

The author thanks to Dr. K. Yokoyama and Prof. T. Mariko for their supervision and encouragement in throughout this study. Thanks are also to Dr. T. Higashino for his helpful advise, Ms. K. Morii for offering her polished thin

sections, and Ms. M. Shigeoka for her helpful advise on the electron microprobe analyses. The author would like to acknowledged the assistance of XRF analyses by Mr. I. Ando.
